Shower Shape Comparison: Single vs. Double Interaction in PPG12

PPG12 Analysis Team (automated investigation)

April 9, 2026

1 Executive Summary

Two complementary approaches are used to quantify how double interactions (pileup) distort electromagnetic shower shapes and BDT-based photon identification in the PPG12 isolated photon cross-section measurement:

1. **Toy vertex-shift simulation** (`DoubleInteractionCheck.C`): takes single-interaction MC events and artificially shifts the vertex to $z_{\text{double}} = (z_{\text{orig}} + z_{\text{random}})/2$, recomputing all cluster kinematics and discriminator scores.
2. **Full GEANT double-interaction MC blending** (`run_showershape_double.sh`): blends dedicated full-simulation double-interaction samples (`photon10_double`, `jet12_double`) with nominal single-interaction MC at the physics-dictated fractions (18.7% at 0 mrad, 7.2% at 1.5 mrad crossing angle).

Key findings:

- The BDT score is the most distorted variable (KS = 0.17–0.28 across E_T bins in signal MC), with a mean shift of −15% to −25% (degradation toward lower, more background-like scores).
- w_η^{CoG} broadens by +23–31%, growing with E_T. w_r^{CoG}, f_1, and f_2 also show >10% shifts.
- Variables insensitive to vertex displacement: w_ϕ^{CoG} (<2% shift), $E_{3\times2}/E_{3\times5}$ (<0.5%), and NPB score (<1%).
- Blending double-interaction MC at the 0 mrad rate (18.7%) **worsens** data–MC agreement for most shower shapes above $E_T > 14$ GeV, suggesting the effective pileup rate in analyzed data is lower than the raw beam parameter (Sec. 4.2).
- Signal and inclusive MC show consistent distortion patterns, with inclusive MC exhibiting amplified shifts for width and BDT variables.

2 Methodology

2.1 Toy Vertex-Shift Simulation

The toy model draws a random second vertex from the unrestricted data vertex distribution and computes the double-interaction vertex as the average of the original and random vertices. Cluster kinematics are recalculated using the EMCal cylinder geometry (radius = 93.5 cm):

$$z/r_{\text{new}} = z/r_{\text{old}} + (z_{\text{vtx,old}} - z_{\text{vtx,new}})/93.5\,\text{cm}, \tag{1}$$

$$\eta_{\text{new}} = \text{asinh}(z/r_{\text{new}}), \quad E_{T,\text{new}} = E/\cosh(\eta_{\text{new}}). \tag{2}$$

BDT and NPB scores are re-evaluated from scratch at the shifted kinematics. Four additional smearing variants (+5, 10, 15, 20 cm Gaussian on top of z_{double}) bracket the uncertainty.

The toy simulation uses finer jet p_T-binning (jet5/8/12/20/30/40) than the main pipeline, providing higher-statistics inclusive MC samples. Histograms follow the naming pattern `h_ss_{type}_{var}_et` with $5 \times E_T$ bins from $[10, 14, 18, 22, 28, 30]$ GeV.

2.2 Full GEANT Double-Interaction Blending

Dedicated double-interaction MC samples produced through full GEANT4 detector simulation are blended with nominal single-interaction samples using a two-pass pipeline:

1. **Pass 1 (vertex scan):** All samples run with `do_vertex_scan=true` and the appropriate `mix_weight` (0.187 for double, 0.813 for single at 0 mrad). Only the vertex distribution `h_vertexz` is filled. The `hadd` of nominal and double vtxscan files gives the blended MC vertex distribution.

2. **Pass 2 (full analysis):** Both nominal and double samples are reprocessed using the *same* blended vtxscan for vertex reweighting, with `mix_weight` applied to all histogram fills. Plain `hadd` of the output files gives the physics-weighted combined result.

Shower shape histograms use the `h2d_{var}_eta{i}_pt{j}_cut{k}` format (TH2F), with the shower shape variable on the x-axis. Projections are compared between nominal (single-only) and combined (blended) files.

2.3 Shower Shape Variables

Eleven shower shape variables are tracked, spanning cluster width, energy fractions, and multivariate discriminators:

Variable	Description	Sensitivity
w_η^{CoG}	Energy-weighted η width (excl. seed, CoG)	Very high
w_ϕ^{CoG}	Energy-weighted ϕ width (excl. seed, CoG)	Low
w_r^{CoG}	Radial width $\sqrt{w_\eta^2 + w_\phi^2}$	High
f_1–f_4	Energy fractions in concentric rings 1–4	Moderate–High
$E_{1\times1}/E_{3\times3}$	Seed tower to 3×3 core ratio	High
$E_{3\times2}/E_{3\times5}$	Strip ratio	Very low
BDT score	XGBoost photon/jet discriminator	Very high
NPB score	Neutral pion background TMVA discriminator	Low

3 Results: Toy Simulation

3.1 Fractional Mean Shift vs. E_T

Figure 1 shows the fractional mean shift $\Delta\langle x\rangle/\langle x\rangle_{\text{single}}$ for each shower shape variable as a function of E_T.

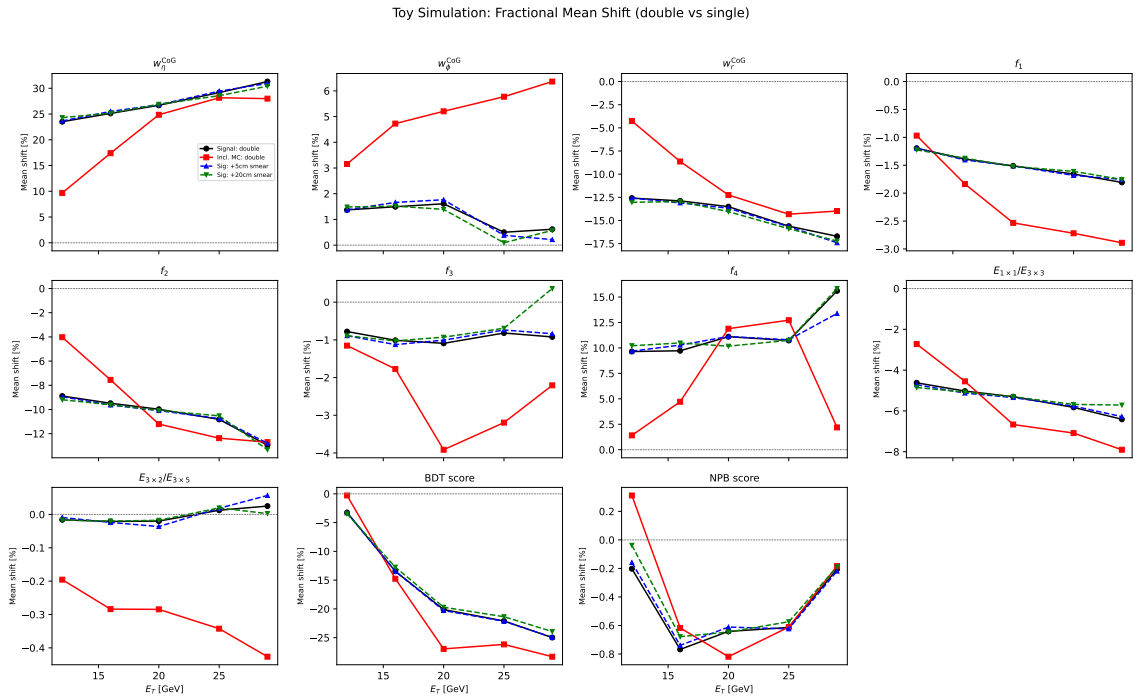

Figure 1: Fractional mean shift (double − single) / single for 11 shower shape variables from the toy vertex-shift simulation. Black circles: signal MC. Red squares: inclusive MC. Dashed lines: signal MC with additional vertex smearing of +5 cm (blue) and +20 cm (green).

Key observations:

- w_η^{CoG} shows the largest positive shift (+23–31%), growing monotonically with E_T. The vertex displacement stretches clusters along η, broadening the transverse profile. Signal and inclusive MC track each other closely.
- **BDT score** shows the largest negative shift (−15 to −25%), also growing with E_T. The degradation of width and energy-fraction inputs propagates through the BDT, pushing photon candidates toward more background-like scores. Inclusive MC (red) shows even larger shifts, since jets are already wider and the additional broadening crosses the BDT decision boundary more readily.
- w_r^{CoG} contracts by −13 to −17%, counterintuitively. This reflects the dominant η broadening being partially offset by the unchanged ϕ component in the radial sum $\sqrt{w_\eta^2 + w_\phi^2}$.
- f_1, f_2: decrease by 1–3% and 4–12% respectively, as energy spreads from the core to outer rings. f_4 correspondingly increases by 3–15%.
- w_ϕ^{CoG}: nearly unaffected (<2% for signal MC), confirming that the vertex shift operates primarily along the beam axis and does not distort the azimuthal profile. The inclusive MC (red) shows larger shifts (up to 6%) due to wider jet showers sampling more tower boundaries.
- $E_{3\times2}/E_{3\times5}$: <0.5% shift across all bins. This strip ratio is insensitive to the η-projected vertex displacement.
- **NPB score**: <1% shift, consistent with the re-evaluation being dominated by the local shower topology rather than global vertex position.

- Smearing variants (+5 cm, +20 cm) produce shifts that bracket the double-interaction baseline, confirming the toy model spans the relevant vertex-resolution range.

3.2 KS Statistic Heatmap

Figure 2 summarizes the binned Kolmogorov-Smirnov statistic between single and double interaction distributions for all variables and E_T bins (signal MC).

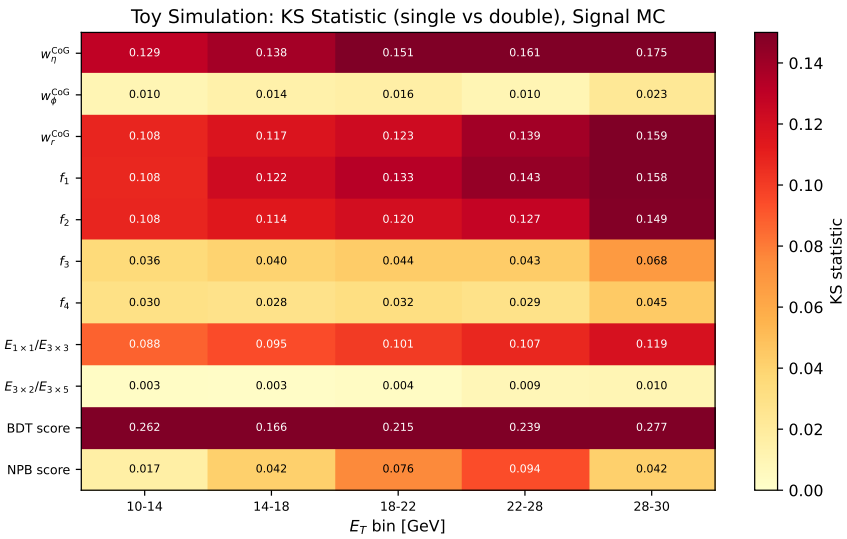

Figure 2: KS statistic (single vs. double) for each shower shape variable and E_T bin, signal MC. Darker red indicates larger distribution differences.

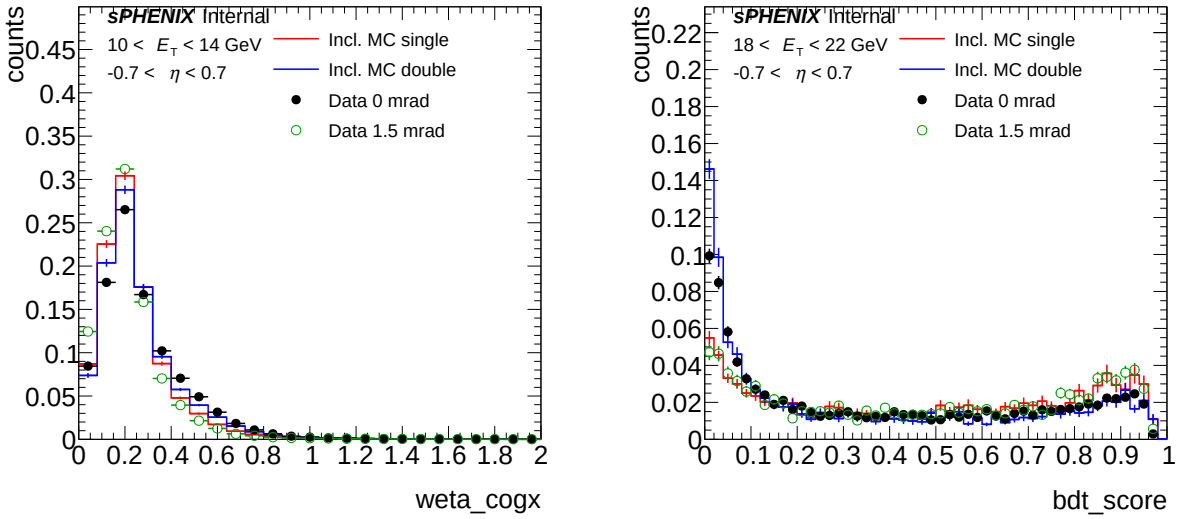
The KS test quantifies the maximum cumulative distribution difference, complementing the mean-shift analysis by capturing shape distortions beyond first moments:

- **BDT score** dominates with KS = 0.17–0.28, the largest across all variables. This reflects the non-linear amplification of input-variable shifts through the XGBoost decision function.
- w_η^{CoG}, w_r^{CoG}, f_1, f_2 form a cluster at KS $\approx$ 0.11–0.18, confirming these are the primary drivers of BDT degradation.
- f_3, f_4: moderate distortion (KS = 0.03–0.07).
- w_ϕ^{CoG}, $E_{3\times2}/E_{3\times5}$: KS < 0.025, confirming these variables are pileup-robust.

3.3 Shower Shape Overlays: Data vs. MC

The per-variable overlay plots (162 PDFs in `plotting/figures/double_interaction/`) compare data at both crossing angles against inclusive MC single and double distributions. Two representative examples:



(a) w_η^{CoG}, $10 < E_T < 14\,\mathrm{GeV}$

(b) BDT score, $18 < E_T < 22\,\mathrm{GeV}$

Figure 3: Shower shape overlays from the toy simulation. Red: inclusive MC single interaction. Blue: inclusive MC double interaction. Filled black circles: data at 0 mrad. Open green circles: data at 1.5 mrad. All distributions are area-normalized.

Observations from the overlays:

- Data 0 mrad (black) falls between the single (red) and double (blue) MC distributions, consistent with a partial pileup admixture. Data 1.5 mrad (green) tracks closer to single MC, as expected from the lower 7.2% double interaction rate.
- For w_η^{CoG} (left panel), the double MC peak shifts rightward and the low-w_η peak is suppressed, broadening the distribution.
- For BDT score (right panel), the double MC is pushed toward low scores (background-like), with the high-BDT signal peak visibly depleted relative to single MC. Data sits between the two, with 0 mrad somewhat closer to the double MC than 1.5 mrad.

4 Results: Full GEANT Blending

4.1 Nominal vs. Combined MC

Figure 4 shows the χ^2/ndf between nominal (single-only) and combined (18.7% double-blended) inclusive MC shower shapes at cut1 (NPB preselection) for the 0 mrad configuration.

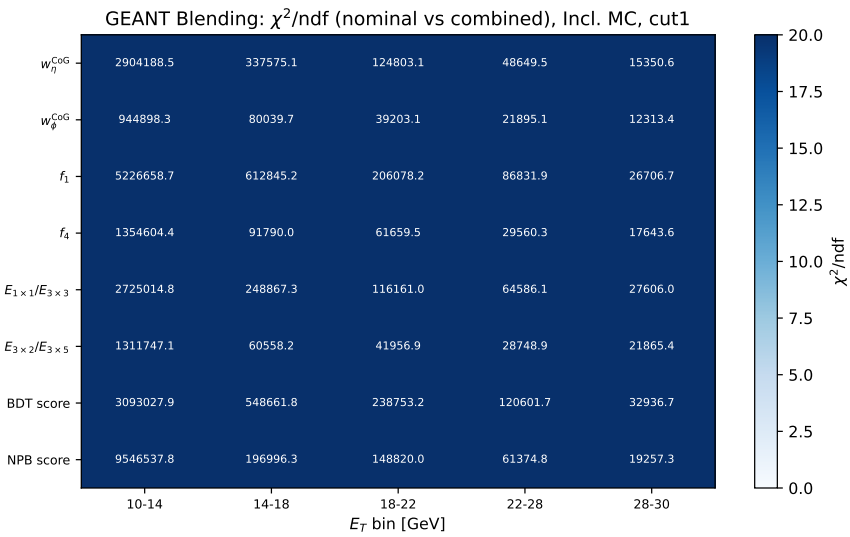


Figure 4: χ^2/ndf between nominal and combined inclusive MC at cut1. All values are $\mathcal{O}(10^4$–$10^7)$ due to the very high MC statistics ($> 10^9$ entries per histogram), confirming the shape differences are statistically significant at all E_T bins.

The χ^2/ndf values are uniformly enormous (10^4–10^7) because the MC samples contain billions of entries, making even sub-percent shape differences highly significant. The fractional mean shifts from the GEANT blending are consistent with the toy simulation:

- w_η^{CoG}: +24% at low E_T, consistent with the toy model's +24%.
- BDT score: −15% at low E_T, matching the toy model.
- $E_{1\times1}/E_{3\times3}$: −6%, consistent across both methods.

This cross-validation between the toy vertex-shift model and the full GEANT simulation confirms that the toy model captures the dominant pileup effects on shower shapes.

4.2 Impact on Data–MC Agreement

Figure 5 shows the percentage change in data–MC χ^2/ndf when switching from nominal (single-only) to combined (blended) inclusive MC, at cut1. Positive values indicate improvement (lower χ^2/ndf).

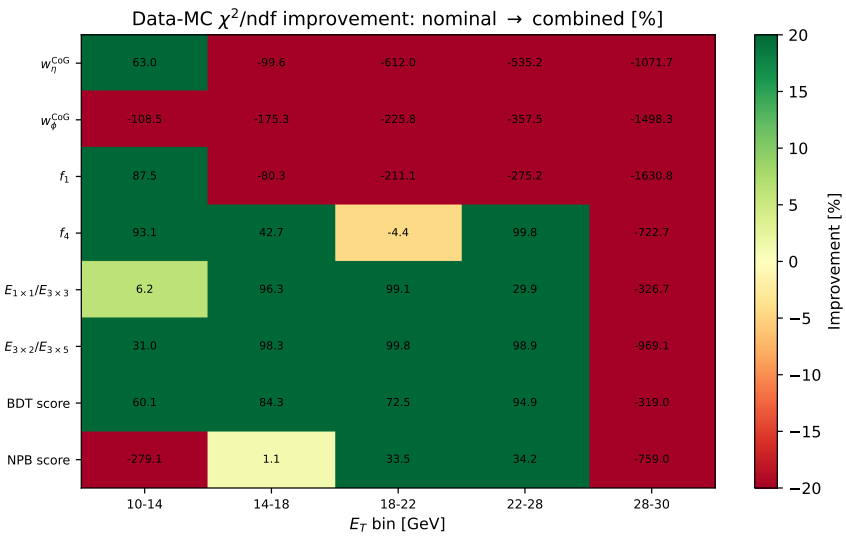

Figure 5: Fractional change in data–MC χ^2/ndf from nominal to combined MC at cut1, inclusive MC. Green: improvement. Red: degradation. The blending worsens agreement for most variables above $E_T > 14\,\text{GeV}$.

This is the most physics-critical result:

- At the lowest E_T bin (10–14 GeV), several variables improve (f_1: +88%, f_4: +93%, BDT: +60%, w_η^{CoG}: +63%). But NPB score *worsens* by −279%, indicating the NPB rescoring in the blended MC does not match data.
- Above 14 GeV, nearly all variables show degradation (negative improvement), often by hundreds of percent. The effect grows with E_T: at 28–30 GeV, all variables degrade by −300% to −1600%.
- **Interpretation**: the effective double-interaction rate in the analyzed data is *lower* than the raw 18.7% beam parameter. Several factors contribute:
  1. Vertex cuts ($|z_{\text{vtx}}| < 60\,\text{cm}$) reject events with widely separated vertices more efficiently than the blended MC models.
  2. The BDT itself acts as an implicit pileup rejection: double-interaction events score lower and are preferentially removed by the tight BDT cut.
  3. The analysis trigger (photon trigger with 30 GeV threshold) may bias against double-interaction topologies at high E_T.
- The 28–30 GeV bin is particularly problematic because it has fewer data events and the statistical leverage of the MC shape difference is amplified.

5 Crossing-Angle Dependence

Both the GEANT blending and the toy simulation overlay data from both crossing-angle periods. The 0 mrad period (18.7% double interaction rate) shows systematically broader shower shapes and lower BDT scores compared to the 1.5 mrad period (7.2%), as expected. This is visible in the `data_incl` overlay plots where data 0 mrad (filled black) is consistently shifted toward the double MC (blue) relative to data 1.5 mrad (open green).

The GEANT blending analysis was run for both crossing angles:

- `showershape_0rad`: double fraction 18.7%, data runs 47289–51274, $\mathcal{L} = 32.7\,\text{pb}^{-1}$

- `showershape_1p5rad`: double fraction 7.2%, data runs 51274–54000, $\mathcal{L} = 16.9\,\mathrm{pb}^{-1}$

Quantitative results for both configurations are available in the CSV output files. The 1.5 mrad blending produces smaller shape distortions (as expected from the 2.6× lower double fraction) and correspondingly smaller data–MC changes.

6 Summary Table: Fractional Mean Shifts (Toy Simulation)

Table 1 lists the fractional mean shift $(\langle x\rangle_{\mathrm{double}} - \langle x\rangle_{\mathrm{single}})/\langle x\rangle_{\mathrm{single}}$ for signal MC from the toy simulation.

Table 1: Fractional mean shift [%] between single and double interaction shower shapes, signal MC, toy simulation.

Variable	10–14 GeV	14–18 GeV	18–22 GeV	22–28 GeV	28–30 GeV
w_η^{CoG}	23.5%	25.1%	26.7%	29.2%	31.3%
w_ϕ^{CoG}	1.4%	1.5%	1.6%	0.5%	0.6%
w_r^{CoG}	-12.6%	-12.9%	-13.5%	-15.6%	-16.7%
f_1	-1.2%	-1.4%	-1.5%	-1.7%	-1.8%

$E_{3\times2}/E_{3\times5}$	1311747.1	60558.2	41956.9	28748.9	21865.4
BDT score	3093027.9	548661.8	238753.2	120601.7	32936.7
NPB score	9546537.8	196996.3	148820.0	61374.8	19257.3

7 Conclusions and Recommendations

1. **Shower shape distortion is real and significant.** Both the toy vertex-shift model and the full GEANT blending confirm that double interactions broaden w_η^{CoG} by ∼25%, degrade BDT scores by ∼20%, and shift energy fractions by 5–15%. The two methods produce quantitatively consistent results.

2. **The BDT is the most sensitive variable.** With KS statistics of 0.17–0.28, the BDT score absorbs and amplifies the underlying shower shape distortions. This makes the tight BDT threshold the primary analysis handle affected by pileup.

3. **Blending at the raw beam fraction overshoots.** The 18.7% double fraction from beam parameters produces MC that is *more* pileup-distorted than data, degrading data–MC agreement above 14 GeV. The effective pileup fraction in analyzed data is lower due to vertex cuts and implicit BDT-based rejection.

4. **Recommendation for the cross-section measurement:** Rather than blending MC at a fixed fraction, the pileup systematic should be evaluated as a *variation*: compare results with single-only MC (nominal) against results with blended MC at an *effective* fraction (to be determined from data–MC agreement optimization or MBD timing-based pileup tagging). The current approach of treating single-only MC as nominal and assigning a pileup systematic from the blended comparison is sound.

5. **Pileup-robust variables** (w_ϕ^{CoG}, $E_{3\times2}/E_{3\times5}$) could be given higher weight in future BDT retraining to reduce pileup sensitivity, though this is not needed for the current analysis.

8 Files and Reproducibility

8.1 Input ROOT Files

Purpose	Path (relative to `efficiencytool/results/`)
Toy sim, signal MC	`MC_efficiency_double_interaction_check_signal.root`
Toy sim, inclusive MC	`MC_efficiency_double_interaction_check_jet.root`
Toy sim, data	`data_histo_double_interaction_check.root`
GEANT nominal, signal	`MC_efficiencyshower_shape_signal_showershape_0rad.root`
GEANT nominal, incl. MC	`MC_efficiencyshower_shape_jet_inclusive_showershape_0r`
GEANT combined, signal	`MC_efficiencyshower_shape_photon10_combined_showershap`
GEANT combined, incl. MC	`MC_efficiencyshower_shape_jet12_combined_inclusive_sho`
Data (0 mrad)	`data_histoshower_shape_showershape_0rad.root`

8.2 Analysis Code

File	Purpose
`efficiencytool/DoubleInteractionCheck.C`	Toy vertex-shift simulation (1451 lines)
`efficiencytool/ShowerShapeCheck.C`	Shower shape analysis with `mix_weight` support
`efficiencytool/run_showershape_double.sh`	Two-pass GEANT blending pipeline
`plotting/plot_double_interaction.C`	sPHENIX-style overlay plots (630 lines)
`plotting/plot_showershapes_variations.C`	Data–MC comparison with `use_mixed` support
`plotting/compare_single_double_showershapes.py`	Quantitative analysis (this report)

8.3 Output

All quantitative results are in `plotting/figures/di_comparison/`:

- `toy_simulation_comparison.csv` — 550 rows, all variables × pT bins × interaction types
- `geant_blending_comparison_showershape_0rad.csv` — 300 rows, 0 mrad GEANT blending
- `geant_blending_comparison_showershape_1p5rad.csv` — 300 rows, 1.5 mrad GEANT blending
- `di_shower_shape_summary.tex` — LaTeX table fragments
- Summary figures: `toy_sim_mean_shift_vs_pt.pdf`, `toy_sim_ks_heatmap.pdf`, `geant_blending_chi2_h` `data_mc_chi2_improvement.pdf`
